From Schema to Spine: Integrating HorrorPlace Personas with Events, Regions, and Styles via NDJSON Contracts

The Persona Taxonomy: A Spectrum of Agency and Interaction

The HorrorPlace constellation defines its inhabitants through a formal, machine-governed taxonomy of persona types, moving beyond ad-hoc character creation to a structured framework where every entity is a "contracted agent" [1]. This approach treats horror as a governed system rather than a creative output, with personas existing as declarative nodes within a larger, queryable universe [1]. The primary axis for this classification is the `personaType` field, which distinguishes between four fundamental categories: `npc`, `spectral-entity`, `environmental-agent`, and `narrative-voice`. Each type represents a different point on a spectrum of agency, interaction, and narrative function, from grounded humanoids to disembodied narrators and sentient environments [1]. This taxonomy is not merely descriptive; it dictates the mandatory fields and semantic expectations for a persona's contract, ensuring that its behavior is consistent with its intended role within the game world's history and mechanics.

The `npc` (Non-Player Character) persona type represents the most conventional form of interaction, functioning as a conversational or transactional entity within the game world [1]. Its contract is designed around dialogue, quest progression, and resource exchange. The `behaviorProfile` for an `npc` would contain parameters related to conversation pacing, inventory states, and quest flag management, aligning with established RPG conventions. Despite being grounded characters, these personas are deeply integrated into the constellation's systemic design. They are instrumented with `metricInfluence` targets to measure their contribution to the player's experience and are subject to `invariantCoupling` rules that tie their existence to the region's historical plausibility. For example, an `npc`'s reliability or knowledge base might be modulated by the `AOS` (Archival Opacity Score) of their location, ensuring that information provided feels contextually appropriate and verifiable within the game's lore [1].

In contrast, the `spectral-entity` persona type embodies the supernatural and paranormal, representing apparitions, hauntings, or glitches in reality [1]. The contract for such a persona explicitly prioritizes grounding its existence in the game's historical data layer to maintain a sense of dread rooted in past trauma. Key fields include the `spectralConsistencyIndex` (SHCI), which quantifies how closely the entity's behavior adheres to evidence from historical sources, and `invariantCoupling` tuned to factors like the `SPI` (Spectral Plausibility Index) [1]. Their behaviors are often abstracted away from complex dialogue trees and focus on manifestation rules, stalking patterns, and environmental manipulation. Due to their complexity and potential for violating established safety norms, `spectral-entity` personas are typically gated behind higher access tiers, such as `vault` or `lab`, requiring cryptographic proof of entitlement before they can be instantiated [1] [20].

The `environmental-agent` category pushes the concept of agency beyond sentient beings, assigning it to non-sentient but reactive systems like architecture, weather, or ambient phenomena [1]. Personas of this type could manifest as corridors that shift unnaturally, winds that carry whispers, or localized gravity anomalies. Their contracts are decoupled from humanoid motivations and instead bind their behavior directly to environmental invariants. For instance, a Process-God archetype would have a `behaviorProfile` controlling geometry deformation and an `invariantCoupling` that triggers its actions when the `CIC` (Catastrophic Imprint Coefficient) or `LSG` (Liminal Stress Gradient) spikes [9]. This allows the environment itself to become a hostile, responsive force, creating emergent horror scenarios that arise from the world's intrinsic properties rather than a directed antagonist [1]. The contract for an `environmental-agent` emphasizes dynamic response over static narrative, making it a powerful tool for generating unpredictable atmospheric tension.

Finally, the `narrative-voice` persona type operates at the meta-narrative level, delivering information without direct interaction [1]. These entities represent radio broadcasts, diary entries, internal monologues, or other forms of disembodied narration. Their primary function is to manipulate the player's perception and psychological state by controlling the flow of lore and contradiction [7]. Their `metricInfluence` is focused on EMD (Evidential Mystery Density) and CDL (Cognitive Dissonance Load), measuring their effectiveness in creating mystery and psychological strain [1]. The `historicalAnchor` is particularly critical for this type, as it ties the voice to specific events and archival sources, ensuring that the information it dispenses maintains internal consistency with the game's overarching history [1]. An Archivist archetype, for example, would use this persona type to gatekeeper knowledge, selectively revealing fragments of documents and introducing conflicting accounts to challenge the player's understanding

of the truth [7]. This type of persona is a master of psychological horror, shaping the player's mental model of the world from the shadows.

Persona Type	Primary Function	Key Contract Fields	Typical Behaviors	Example Archetype
`npc`	Conversation, Quests, Transactions	`dialogueTree`, `inventory`, `questState`	Dialogue branching, item trading, objective givers	Mysterious Operator
`spectral-entity`	Haunting, Manifestation, Stalking	`spectralConsistencyIndex`, `SPI`, `manifestationRules`	Appearing/disappearing, chasing players, environmental effects	Vanished Researcher
`environmental-agent`	Environmental Reaction, Emergent Threats	`deformGeometry`, `reactToInvariants`	Shifting architecture, anomalous weather, whispering winds	Process-God
`narrative-voice`	Lore Delivery, Mystery Creation, Psychological Pressure	`deliverLore`, `fragmentedNarrative`, `reliabilityWeight`	Radio broadcasts, diary entries, distorted messages	Chief Archivist

This taxonomy provides a robust vocabulary for designers, allowing them to precisely specify a persona's role and constraints within the constellation's governing schema [1]. By defining personas as contractual agents, the system ensures that every entity, from a simple vendor to a god-like environmental force, is a predictable, integrable component of the larger horror ecosystem, governed by the same principles of historical anchoring, dynamic adaptation, and experiential measurement.

The Persona Contract: Core Structure and Validation

At the heart of the HorrorPlace constellation's persona system lies the NDJSON registry entry, a formal contract that defines an entity's identity, origin, behavior, and relationship to the game world [1]. This contract is not a creative document but a machine-readable specification that guarantees consistency, discoverability, and enforceability across the entire system [15]. Every persona entry, regardless of its `personaType`, conforms to a base set of required fields that establish its provenance, status, and governance [1]. These foundational fields include `id`, `schemaref`, `deadledgerref`, `artifactid`, `createdAt`, and `status`, forming a standardized header for every persona contract [1]. Following these base requirements are persona-specific fields—`personaType`, `historicalAnchor`, `behaviorProfile`, and `invariantCoupling`—which together constitute the core logic of the agent [1].

The `id` field is the cornerstone of the registry's discovery mechanism, providing a globally unique, immutable identifier for the persona [1]. It follows a strict `<TYPE>-<REGION-CODE>-<SEQUENCE>` pattern, where `<TYPE>` is "PER", `<REGION-CODE>` is a code derived from the region it primarily inhabits (e.g., "ARAL"), and `<SEQUENCE>` is a zero-padded four-digit number (e.g., "0001") [1]. This structure ensures that every persona has a stable, predictable name that can be used to reference it from any other registry file without ambiguity, replacing guesswork and hardcoded paths with a robust, queryable index [1]. Once a persona is published with an ID, that ID cannot be changed; if modifications are needed, a new entry with a new ID must be created, and the old one deprecated with a `deprecatedReplacedBy` field [1].

The remaining base fields serve a crucial role in governance and asset management. The `schemaref` field contains the canonical URI of the JSON Schema that the entry must conform to, acting as the ultimate authority on its structure and data types [1]. This enables automated validation tools to verify the contract's integrity against a known standard. The `deadledgerref` field holds an opaque reference to a cryptographic proof or governance ledger entry, which can be used to validate the creator's entitlement to publish the persona, especially for assets in gated tiers like `vault` or `lab` [1]. Similarly, the `artifactid` provides an opaque, content-addressable reference to the actual implementation asset—for example, a compiled behavior tree, an animation asset, or a script—which may reside on IPFS, in a private Git repository, or elsewhere [1]. This separation of the contract from the raw asset is fundamental to the system's design, keeping public repositories clean and safe while maintaining a secure link to the underlying implementation [13] [21]. The `createdAt` timestamp records the UTC time of the entry's creation in ISO 8601 format, and the `status` field, an enum of `"active"`, `"deprecated"`, `"archived"`, or `"draft"`, controls the persona's lifecycle and visibility within the constellation [1].

Beyond these universal fields, the persona contract is fleshed out with four persona-specific objects that define its very nature. The `personaType` enum (`"npc"`, `"spectral-entity"`, `"environmental-agent"`, `"narrative-voice"`) determines which additional fields are expected and governs the persona's fundamental role and behavior vocabulary [1]. The `historicalAnchor` object is arguably the most critical, as it grounds the persona firmly in the game's history. It must contain at least a reference to a valid event (`eventRef`) from the events registry, a `role` (e.g., "vanished-researcher"), a `reliabilityWeight` (RWF) to rate the credibility of its source material, and a list of `archivalSources` containing opaque references to supporting

documents [1]. This ensures that every persona is a query result from the history layer, preventing arbitrary creations and enforcing narrative coherence.

The `behaviorProfile` defines the persona's runtime actions and parameters. It is a map of behavior names (e.g., `"stalk"`, `"dialogue"`, `"manifest"`) to their respective configuration objects [1]. The keys are drawn from an approved vocabulary, and the parameters are strictly type-checked by the schema, allowing AI and engine systems to safely wire these behaviors into state machines or action trees [1]. Finally, the `invariantCoupling` object establishes a dynamic relationship between the persona and the world's measurable properties. It maps invariant names (like `CIC` or `AOS`) to a set of response rules that dictate how the persona's behavior should scale or change in response to shifts in those invariants, enabling adaptive and emergent gameplay [1]. Together, these five core objects—the two sets of base and persona-specific fields—form a complete and self-contained contract that tells engines and AI exactly how to instantiate, control, and reason about a given persona.

To enforce these structural rules, the constellation employs a rigorous validation process. All registry files are processed by a linter, `hpc-lint-registry.py`, which performs several checks [1]. It verifies the presence and format of all required fields, confirms that the `schemaref` points to a valid, existing schema, and ensures that the `id` is unique within its file [1]. The linter also enforces tier-specific rules, such as requiring a `deadledgerref` for `vault` or `lab` tier entries and validating that status transitions follow allowed paths (e.g., a `draft` entry can become `active`, but not vice versa) [1]. Furthermore, it validates the contents of persona-specific fields: it checks that `personaType` is one of the allowed enums, that `historicalAnchor.eventRef` points to a real event, that `behaviorProfile` uses only approved behavior names and parameter types, and that `invariantCoupling` keys match known invariants with syntactically correct response rules [1]. This comprehensive, CI-integrated linting process ensures that the entire constellation remains a coherent, reliable, and auditable system of contracts.

Mechanisms of Integration: Binding Personas to the Constellation

Personas in the HorrorPlace constellation are not isolated actors but are deeply woven into the fabric of the game world through a sophisticated system of integration. This

system replaces traditional, path-based dependencies with a declarative, registry-driven network of relationships, binding personas to events, regions, and styles through explicit ID-based cross-referencing [1]. This creates a highly interconnected and navigable universe where an AI orchestrator or game engine can programmatically discover what exists, understand how elements relate to one another, and make informed decisions about content scheduling and instantiation. The foundation of this integration is the globally unique, stable ID assigned to every registry entry, including personas (`PER-*`) [1]. This ID serves as the universal key for establishing connections, enabling bidirectional lookup and dependency resolution without any hardcoding of file locations or repository URLs [1].

The primary mechanism for binding personas to other parts of the constellation is through direct referencing in other registry entries. An event, defined in the `events` registry, can declare which personas are capable of appearing during its occurrence. The `events` schema specifies an optional `personaIds` array, which is a list of persona IDs [1]. When an AI drama manager schedules an `encounter` event, it queries the registry using the event's ID to retrieve its associated persona list. This ensures a tight, explicit link between a scenario and its cast, guaranteeing that only authorized personas participate in a given situation. Conversely, a region's contract can implicitly or explicitly define which personas are active within its bounds. While a region's primary linkage is to events via the `regionIds` array, a region's `invariantProfile` and `biomeTags` determine the suitability of its inhabitants [1]. A persona's `invariantCoupling` and its own `tier` (public, vault, lab) must be compatible with the region's profile for it to be considered a valid inhabitant [1]. Tools can leverage the spine index—a centralized mapping of all IDs to their owning registries—to traverse these links in either direction. For example, given a persona ID, a tool can efficiently query for all events it participates in, all regions where it is valid, and all styles that apply to it, building a complete dependency graph [1].

This ID-based referencing extends to the aesthetic layer as well, mediated through the `styles` registry. A persona's behavior might be tied to specific audio cues, visual effects, or narrative tones that are themselves defined in style contracts [1]. A persona's `behaviorProfile` might reference an audio cue named `"distorted-whisper"`, which would then be mapped to a specific sound asset by a style applied to the region where the persona appears. The `styles` registry itself is linked bidirectionally; a region can list valid `styleIds`, and a persona contract can inherit or override style-related parameters through its own fields [1]. The `prismMetaRef` field further enhances this web of connections by providing a reference to a separate metadata document that can describe more complex dependency graphs, enabling advanced tooling for validation and

analysis [1]. This creates a multi-layered system where a single persona contract can be connected to a chain of assets, events, regions, and styles, all resolved through a common language of opaque, stable IDs.

The following table illustrates the cross-referencing relationships between persona contracts and other registry types:

Registry Type	Referenced Via	Purpose of Linkage
Events	`eventRegistryEntry.personaIds: ["PER-..."]`	Declares which personas are valid participants in the event's scenario.
Regions	`personaContract.invariantCoupling` & `tier` vs. `regionContract.invariantProfile` & `tier`	Determines the compatibility and validity of a persona for a given location.
Styles	`personaContract.behaviorProfile` (references style-defined cues) & `prismMetaRef`	Defines the aesthetic presentation and behavioral tone of the persona.

This registry-centric architecture is a deliberate choice to promote scalability and platform independence. Because all components are identified by abstract IDs rather than concrete file paths, the system can support multiple game engines (e.g., Unreal, Godot) and platforms simultaneously [15]. An engine author needs only to implement a resolver that can translate a given persona ID into an executable asset, without needing to understand the internal structure of other registries. This abstraction layer allows the creative and design teams to iterate on events, regions, and personas independently, confident that the registry linter will catch any broken links or invalid dependencies before they reach production [1]. The result is a resilient and evolving design space where personas are not just characters but are first-class citizens in a vast, interconnected data graph, whose existence and interactions are governed by a transparent, auditable, and machine-enforceable set of contracts.

Invariant Coupling: Dynamic Adaptation Through Data

While ID-based cross-referencing establishes the static skeleton of the HorrorPlace constellation, `invariant coupling` provides the dynamic muscle that allows personas to adapt to the evolving state of the game world. Invariants are measurable, quantitative properties of the environment and narrative that reflect its history and current condition [1]. Key examples include the Catastrophic Imprint Coefficient (CIC), which measures the residue of traumatic events; the Archival Opacity Score (AOS), which reflects the difficulty of uncovering historical truths; and the Dread Threshold (DET), which gauges

the ambient level of fear [1]. A persona's contract can declare a `invariantCoupling`, which is an object that maps these invariant names to a set of behavior-response rules [1]. This mechanism couples a persona's potential for action to the world's current state, allowing a single persona definition to generate vastly different experiences depending on the context in which it manifests, thus creating a powerful engine for emergent and responsive horror.

The `invariantCoupling` object provides a flexible vocabulary for designers to articulate how a persona's behavior should change in response to fluctuating invariant values. The value for each invariant is itself an object containing one or more tuning parameters. These parameters can take several forms, each offering a different way to modulate behavior. Multipliers, such as `"aggressionMultiplier": 1.5`, provide a straightforward way to scale a numerical parameter up or down. If the live value of the coupled invariant meets a certain condition, the multiplier is applied at runtime. Thresholds, expressed as strings like `">=0.7"`, allow for conditional activation. For example, a persona might only trigger a specific, high-intensity audio cue if the AOS exceeds 0.7 [1]. Scaling functions, like `"linear-scale"`, offer a continuous transformation, where a persona's intensity might increase proportionally as the CIC rises from 0 to 1 [1]. This rich syntax allows for fine-grained control over a persona's emergence and intensity without requiring changes to its underlying code or contract.

This coupling is a prime example of indirect or Gibson's direct coupling, where the agent's behavior is functionally linked to the environment's state [8]. Instead of the persona having a fixed aggression level, its aggression becomes a function of the region's CIC. A `spectral-entity` anchored to a high-CIC bio-weapon trial event, for instance, would naturally feel more aggressive and dangerous within the contaminated labs of that event's location than in a peripheral, low-CIC storage room [1]. This ensures that the horror remains plausible and thematically consistent. The same `Witness` persona could stalk a player with greater ferocity in a zone of intense historical trauma, reflecting the lingering rage of the event itself. This data-driven approach allows for a more organic and believable ecosystem of horror, where threats scale with the perceived danger of the environment.

The following table details how `invariantCoupling` can be used to tune different persona types for dynamic adaptation:

Persona Type	Coupled Invariant(s)	Response Rule Example	Effect on Persona
`spectral-entity`	`CIC`, `AOS`	`"CIC": {"aggressionMultiplier": 1.5}`	Becomes more aggressive and likely to manifest in areas of high historical trauma.
`narrative-voice`	`AOS`	`"AOS": {"audioPitchShift": ">0.7"}`	Audio delivery becomes more distorted and unsettling in areas shrouded in mystery.
`environmental-agent`	`LSG`, `DET`	`"LSG": {"triggerThreshold": ">=0.8"}`	Deforms geometry only in highly liminal spaces under extreme stress conditions.
`npc`	`AOS`	`"AOS": {"dialogueFragmentation": "linear-scale"}`	Provides more cryptic and fragmented information in places where history is deliberately obscured.

The linter enforces the validity of these couplings, ensuring that all referenced invariants exist in the canonical `invariants-spine.v1.json` and that the response rules use only the approved syntax [1]. This formal validation preserves the integrity of the system, preventing malformed or nonsensical coupling rules from entering the constellation. By embedding this dynamic adaptation logic directly into the persona's contract, the system makes it possible to create a wide variety of challenging encounters from a relatively small pool of persona definitions. It shifts the designer's focus from scripting every possible permutation of an encounter to designing the core behaviors and defining the rules by which those behaviors respond to the world. This results in a more scalable and sustainable design workflow, capable of generating a rich tapestry of emergent, context-sensitive horror experiences.

Metric Influence: Guiding Procedural Horror

Beyond their immediate interactions, personas in the HorrorPlace constellation are designed to contribute to the overall player experience in a measurable way. This contribution is captured in the `metricInfluence` field of a persona's contract, which articulates the persona's intended effect on a suite of entertainment and telemetry metrics [1]. Metrics such as UEC (Unplanned Event Count), EMD (Evidential Mystery Density), STCI (Suspense-to-Chaos Ratio Index), CDL (Cognitive Dissonance Load), and ARR (Anxiety-Related Response) are used to quantify aspects of the player's journey, from the frequency of scares to the depth of the mystery they are immersed in [1]. By assigning personas explicit `metricInfluence` targets, the system transforms them from passive objects or scripted antagonists into active participants in the game's pacing and emotional arc. This creates a feedback loop where the drama manager can make strategic, data-

informed decisions about which personas to schedule to achieve a desired experiential outcome, effectively guiding the procedural generation of horror.

The `metricInfluence` object is structured as a map, with metric names as keys and target ranges as values [1]. The target range is typically an array, `[min, max]`, indicating the desired change in the metric's value upon a successful persona interaction. To signify an increase, a `+` prefix is used, as in `{"EMD":{"+":[5,15]}}`, meaning the persona's appearance and interaction should raise the EMD by a minimum of 5 and a maximum of 15 points [1]. This allows designers to precisely calibrate a persona's role in the narrative. For example, a `narrative-voice` persona designed to drip-feed cryptic lore would be given a high positive `metricInfluence` for EMD and CDL, signaling its purpose to deepen the mystery and create cognitive strain [1]. Conversely, a `spectral-entity` built for jump-scares would have a strong positive influence on UEC and STCI, targeting moments of high suspense and chaotic confrontation [1].

This system empowers a central drama manager to orchestrate the player's experience. Instead of simply triggering events randomly, the manager can consult the `metricInfluence` of all available personas to select the next actor that best fits the current desired state of the session's metrics. If the current EMD is low and the goal is to build intrigue, the manager will prioritize scheduling personas with high positive EMD targets. If the ARR is too low and the goal is to induce panic, it will favor personas with high positive ARR targets. This turns the collection of personas into a palette of tools for the director, each with a specific brushstroke to paint the player's emotional landscape. The `telemetryHooks` field in the event registry complements this by declaring which metrics an event itself emits, allowing the system to correlate designed scenarios with the resulting player experience data for iterative refinement [1].

The following table outlines the typical `metricInfluence` profiles for the archetypal personas discussed previously, illustrating how their design goals are translated into measurable targets:

Persona Archetype	Persona Type	Primary `metricInfluence` Target	Rationale
Archivist	`narrative-voice`	`{"EMD": {"+":[10,25]}, "CDL": {"+":[2,5]}}`	Designed to increase mystery and cognitive dissonance by delivering fragmented lore.
Witness	`spectral-entity`	`{"UEC": {"+":[5,10]}, "STCI": {"+":[0.2,0.5]}}`	Designed to create unplanned encounters and shift the balance from suspense to chaos.
Process-God	`environmental-agent`	`{"ARR": {"+":[20,40]}, "CDL": {"+":[1,3]}}`	Designed to induce acute anxiety and cognitive strain through environmental terror.

By making a persona's experiential impact a first-class citizen in its contract, the system elevates the design process to a higher level of abstraction. Designers can focus on the qualitative feel of an encounter and then use the metric system to quantify and realize that feel in a deterministic and repeatable way. This approach also facilitates data-driven design, as post-mortem analysis of session telemetry can reveal whether a persona's `metricInfluence` targets were met, providing valuable feedback for future iterations. If a `spectral-entity` consistently fails to raise STCI, the `behaviorProfile` or `invariantCoupling` might need adjustment. This closes the loop between design intent and player experience, ensuring that every persona contract is not just a blueprint for an entity, but a promise of a specific kind of horror.

Practical Applications: GitHub-Ready Persona Examples

To ground the theoretical framework of persona contracts in practical application, this section presents concrete, minimal NDJSON entries for three archetypal personas: an Archivist (representing `narrative-voice`), a Witness (representing `spectral-entity`), and a Process-God (representing `environmental-agent`). These examples are designed to be safe for public repositories, adhering strictly to the conventions outlined in the documentation [1]. They use compact, single-line formatting with required fields, relevant optional fields, and placeholder opaque identifiers for artifacts and cryptographic proofs, making them ready for inclusion in a `personas.example.ndjson` file within the `HorrorPlace-Constellation-Contracts` repository [1]. Each example is accompanied by a detailed analysis of its structure and how it leverages the integration mechanisms of the constellation.

Example 1: Archivist (a `narrative-voice` persona)

```
{"id":"PER-ARAL-0001","schemaref":"https://horrorplace.constellation/schem
```

Analysis: This `narrative-voice` persona, an "Archivist," is designed to increase mystery and cognitive strain. It is anchored to the `bio-weapon-trial-1992` event (`EVT-ARAL-0001`) as the "chief-librarian" [1]. The `reliabilityWeight` of 0.6 indicates its information is questionable, fitting for a mysterious figure [1]. Its `behaviorProfile` shows it delivers lore in fragmented lines, but only activates if the player's sanity is above 40, suggesting it avoids fragile players [1]. Crucially, its `invariantCoupling` ensures that in areas of high archival opacity (`AOS > 0.7`), its audio cues become more intense, heightening the dread [1]. Finally, its

`metricInfluence` directly targets a significant increase in both EMD (+10 to +25) and CDL (+2 to +5), fulfilling its core purpose of manipulating the player's understanding of the lore [1].

Example 2: Witness (a `spectral-entity` persona)

```
{"id":"PER-ARAL-0002","schemaref":"https://horrorplace.constellation/schem
```

Analysis: This `spectral-entity` "Witness" is a classic haunting ghost tied to the main atrocity event [1]. Anchored to `EVT-ARAL-0001` as a "survivor," its high `reliabilityWeight` of 0.9 suggests its testimony is credible, yet its spectral nature requires it to be placed in a `vault` tier, justified by its `spectralConsistencyIndex` of 0.85 [1]. Its `behaviorProfile` defines two key actions: `stalk`, which activates when player sanity drops below 50, and `manifest`, which produces a specific audio and visual effect [1]. The `invariantCoupling` is critical: in high-trauma (`CIC`) zones, the entity becomes more aggressive (multiplier of 1.2) and is more likely to manifest, making it a direct threat in the most dangerous areas [1]. Its `metricInfluence` targets a rise in UEC (+5 to +10) and STCI (+0.2 to +0.5), perfectly matching its role as a source of unpredictable encounters and chaotic fear [1].

Example 3: Process-God (an `environmental-agent` persona)

```
{"id":"PER-ARAL-0003","schemaref":"https://horrorplace.constellation/schem
```

Analysis: This `environmental-agent` "Process-God" represents a malevolent force embedded within the environment itself [1]. As an environmental agent, its `behaviorProfile` is entirely abstract, controlling geometry deformation [1]. Its `invariantCoupling` is its defining feature: it is triggered by a high `LSG` (liminal stress gradient) and a high `DET` (dread threshold), making it a reactive entity that appears in transitional spaces under conditions of maximum tension [1]. This exemplifies how agency can be divorced from sentience and tied directly to environmental and psychological states. Its `metricInfluence` targets ARR (+20 to +40) and CDL (+1 to +3), showing it is designed to induce panic and cognitive strain, fulfilling the role of a terrifying environmental hazard [1].
